SUMMARY
When mevalonic acid-2-C\(^{14}\) was incubated with rat liver homogenate with the usual cofactors plus \(10^{-3}\) M arsenite, the formation of labeled cholesterol was inhibited and labeled lanosterol accumulated. This inhibitory effect of arsenite provides a convenient method of preparing labeled lanosterol in high yield (>10%) from commercially available C\(^{14}\)-labeled mevalonic acid.

RESULTS AND DISCUSSION
When MVA-2-C\(^{14}\) was incubated under aerobic conditions with rat liver homogenate and the proper cofactors, substantial amounts of \(^{14}CO_2\) were formed. Addition of arsenite inhibited the formation of \(^{14}CO_2\) without affecting the yield in labeled sterol (Table 1). Chromatography of the nonsaponifiable material revealed that over 90% of the label was associated with the sterols, and that very little \(^{14}C\) was present in the squalene fraction. Since the conversion of MVA-2-C\(^{14}\) to lanosterol would not give rise to labeled \(^{14}CO_2\), whereas the formation of cholesterol should be accompanied by the formation of radioactive \(^{14}CO_2\), it appeared likely that the labeled product was lanosterol. This was confirmed by the following pieces of evidence: (a) When labeled
squalene, prepared by incubating MVA-2-C\textsuperscript{14} with rat liver homogenate under anaerobic conditions, was incubated with rat liver microsomes and soluble proteins, both labeled sterol and labeled CO\textsubscript{2} were formed. The addition of arsenite abolished the formation of CO\textsubscript{2} without affecting the yield of sterol (Table 2). (e) When the labeled sterol, obtained in the presence of arsenite, was recrystallized with cholesterol, the crystals obtained after two recrystallizations had no radioactivity. (e) When the labeled sterol was recrystallized with lanosterol, the radioactivity remained with the crystals after three recrystallizations.

Based on this inhibitory effect of arsenite, labeled lanosterol can be prepared conveniently from MVA-2-C\textsuperscript{14}. A typical experiment follows: Five milliliters of rat liver homogenate was preincubated with 10\textsuperscript{-3} M arsenite for 1 hour at 0\textdegree, and then incubated aerobically for 3 hours at 37\textdegree after the addition of 1 \textmu mole of racemic MVA-2-C\textsuperscript{14}, 10 \textmu moles of DPN\textsuperscript{+}, and 20 \textmu moles of ATP. After saponification, extraction, and chromatography on active alumina, the yield of lanosterol was 0.2 \mu c, or 40\% of the maximum theoretical yield.

10\textsuperscript{6} cpm of squalene was suspended with the aid of 0.5 mg of Tween 80 and incubated for 3 hours with 2 ml of dialyzed rat liver supernatant and microsomes. Addition of arsenite at 10\textsuperscript{-3} M inhibited only C\textsuperscript{14}H\textsubscript{2} formation. The squalene was prepared by the incubation of MVA-2-C\textsuperscript{14} with rat liver homogenate under anaerobic conditions. The supernatant and microsomes were obtained by centrifuging liver homogenate for 30 minutes at 8,000 \times g to remove the mitochondria. The supernatant thus obtained was dialyzed for 3 hours at 2\textdegree against 260 volumes of 0.001 M phosphate buffer (pH 7.0).
