Abstract Adipose tissue contains one of the largest reservoirs of cholesterol in the body. Adipocyte dysfunction in obesity is associated with intracellular cholesterol accumulation, and alterations in cholesterol homeostasis have been shown to alter glucose metabolism in cultured adipocytes. ABCA1 plays a major role in cholesterol efflux, suggesting a role for ABCA1 in maintaining cholesterol homeostasis in the adipocyte. However, the impact of adipocyte ABCA1 on adipose tissue function and glucose metabolism is unknown. Our aim was to determine the impact of adipocyte ABCA1 on adipose tissue function and glucose metabolism in vivo. To address this, we used mice lacking ABCA1 specifically in adipocytes (ABCA1<sup>−/−</sup>). When fed a high-fat, high-cholesterol diet, ABCA1<sup>−/−</sup> mice showed increased cholesterol and triglyceride stores in adipose tissue, developed enlarged fat pads, and had increased body weight. Associated with these phenotypic changes, we observed significant changes in the expression of genes involved in cholesterol and glucose homeostasis, including ldlr, abcg1, glut4, adiponectin, and leptin. ABCA1<sup>−/−</sup> mice also demonstrated impaired glucose tolerance, lower insulin sensitivity, and decreased insulin secretion. We conclude that ABCA1 in adipocytes influences adipocyte lipid metabolism, body weight, and whole-body glucose homeostasis.—de Haan, W., A. Bhattacharjee, P. Ruddle, M. H. Kang, and M. R. Hayden. ABCA1 in adipocytes regulates adipose tissue lipid content, glucose tolerance, and insulin sensitivity. J. Lipid Res. 2014. 55: 516–523.

Supplementary key words cholesterol • glucose homeostasis • insulin resistance • lipid metabolism • obesity • type 2 diabetes • ATP binding cassette transporter A1

Adipose tissue has a crucial role in energy metabolism because it is the major storage site for TGs. Furthermore, adipose tissue is an important exocrine organ secreting various adipokines important in metabolism (1, 2). In addition to being the main site for TG storage, adipose tissue also contains one of the largest pools of cholesterol in the body (3, 4). Cholesterol and TGs are taken up by adipocytes from plasma lipoproteins via lipoprotein receptors including the LDL receptor (LDLR), scavenger receptor B1 (SR-B1), and CD96 (3–5). TGs leave adipose tissue as NEFAs after TG lipolysis (6), while cholesterol is removed from adipocytes via transporters such as ABCA1 and ABCG1 (7, 8).

ABCA1 is responsible for the efflux of cholesterol to apoA1 and small HDL particles and is the rate-limiting protein in HDL production (9, 10). ABCA1 is widely expressed (11), has been shown to be a crucial regulator of intracellular cholesterol stores, and has an important role in the function of multiple tissues (12, 13). For example, lack of ABCA1 in the brain leads to changes in motor activity and sensorimotor function (12), whereas ABCA1 deficiency in beta cells reduces insulin release (14). ABCA1 has been shown to be expressed and functional in adipocytes (7, 8). Gonadal adipose tissue (GAT) lacking ABCA1 has reduced cholesterol efflux concomitant with increased cholesterol stores (9, 15), indicating that ABCA1-mediated cholesterol efflux is important in adipocyte cholesterol metabolism. Changes in adipocyte cholesterol homeostasis are associated with adipose dysfunction and obesity (3, 16, 17). However, the role of ABCA1 and intracellular cholesterol in adipose tissue dysfunction with regard to body weight and glucose metabolism is unclear.

Intracellular cholesterol has been suggested to play a role in adipose tissue dysfunction (3, 16, 17). Adipocytes from obese individuals contain increased stores of both TGs and cholesterol (3, 17). Furthermore, in 3T3 adipocytes, stimulation of TG lipolysis has been shown to induce cholesterol efflux (7). Therefore, it has been suggested that cholesterol may directly affect TG stores (16, 17). This also suggests that ABCA1 may be linked to TG metabolism in adipocytes and adipose tissue function. Adipose tissue

dysfunction is a characteristic of obesity (18) and is an important risk factor for insulin resistance, glucose intolerance, and the eventual development of type 2 diabetes (18, 19). Adipose tissue dysfunction affects glucose tolerance through altered release of NEFAs and adipokines in plasma (1, 2, 19, 20). NEFA release from adipose tissue reduces insulin sensitivity and insulin secretion (19, 21). Expression and release of the various adipokines regulate insulin sensitivity, insulin release, and glucose tolerance (2, 19, 21).

Adipocyte cholesterol may also directly regulate glucose homeostasis in the adipocyte. Membrane cholesterol depletion from the adipocyte using methyl-β-cyclodextrin reduces GLUT-4 expression and impairs insulin-stimulated adipocyte glucose transport in 3T3 cells (16). This provides further evidence for a direct link between cholesterol and adipocyte glucose homeostasis.

Collectively, this evidence suggests that cholesterol regulation in adipocytes may have important implications for glucose homeostasis. ABCA1 has been shown to regulate adipocyte cholesterol levels (7, 8). However, the role of ABCA1 in adipocyte function with regard to body weight and glucose metabolism is unknown. In this study, we suggest a link between the regulation of cholesterol in adipocytes by ABCA1 with TG storage, body weight, and whole-body glucose homeostasis.

MATERIALS AND METHODS

Animals

Mice lacking ABCA1 in the adipose tissue (ABCA1−/−/−) were generated by crossing ABCA1 floxed mice with mice expressing the cre transgene under the adipose-specific aP2 promoter (The Jackson Laboratory, Bar Harbor, ME). These mice have been shown to be deficient in ABCA1 specifically in their adipose tissues (15). Mice were on a C57BL/6 background, were housed under 12 h light-dark cycles, and had ad libitum access to chow or high-fat, high-cholesterol (HFHC) diet and water. Male mice were used for all experiments. To study the role of adipocyte ABCA1 in diet-induced obesity, mice were fed an HFHC diet by ABCA1 with TG storage, body weight, and whole-body glucose homeostasis.

Plasma analysis

Blood samples were drawn from mice from the saphenous vein after 4 h fasting (8 AM to 12 PM). Blood glucose was measured with a glucose meter (OneTouch) or using QuantiChrom glucose assay reagents (BioAssay Systems, Hayward, CA) according to the manufacturer’s protocol. Insulin was measured using the Mouse Insulin ELISA (Mercodia, Uppsala, Sweden). TGs were measured with TG reagent (Roche), HDL cholesterol was measured after precipitation of apolipoprotein-containing lipoproteins from plasma using heparin (500 U/ml) and MnCl2 (0.2 M) 2:1 (22). Adiponectin, visfatin, and leptin were measured with commercially available ELISA kits (adiponectin: Alpcor, Salem, NH; visfatin: Abnova, Taipei City, Taiwan; leptin: Abcam, Cambridge, UK).

Glucose tolerance and insulin sensitivity testing

Mice were fasted for 4 h (8 AM to 12 PM) and were injected intraperitonially with 1 g/kg (HFHC) or 2 g/kg (chow) glucose (Sigma) in PBS for glucose tolerance testing or with 1 U/kg insulin (Novo Nordisk, Bagsvaerd, Denmark) in PBS for insulin sensitivity testing. Blood was drawn via the saphenous vein before injection and at 15, 30, 60, and 90 min after injection and was assayed for glucose.

Insulin secretion

Islets were isolated from mice anesthetized with avertin intraperitonically, and the pancreas was perfused with collagenase (Sigma) in calcium-free HBSS via the bile duct. The pancreas was homogenized after digestion at 37°C, and islets were hand-picked in RPMI 10% FBS and penicillin/streptomycin. For glucose secretion experiments, islets were incubated in Krebs-Ringer Bicarbonate buffer (2 h) followed by 1 h incubation in low- or high-glucose Krebs buffer (167 vs. 16.7 mM). Insulin secretion in the supernatant was assayed using Mouse Insulin ELISA (Mercodia).

Statistical analysis

Data are expressed as means ± SEM. Data were interpreted using Student’s t-test or two-way ANOVA followed by Bonferroni post hoc test using Prism 5.0a (GraphPad, La Jolla, CA). Differences were considered statistically significant when P < 0.05.
RESULTS

Adipocyte ABCA1 deficiency increases adipose tissue cholesterol content

ABC1 protein expression in adipose tissue was measured by Western blotting to confirm the specific loss of ABC1 in adipose tissue from ABC1−/−/− mice. A significant reduction in adipocyte ABC1 protein levels in ABC1−/−/− mice was observed (Fig. 1A). To ensure that ABC1 knockdown due to expression of the ap2-cre transgene was only localized to adipocytes, we also measured ABC1 in liver, muscle, and brain and found no change in ABC1 protein levels (supplementary Fig. IA).

Because ABC1 is a major mediator of cholesterol efflux (9, 10), we evaluated whether loss of ABC1 in adipocytes raises adipose cholesterol content. We observed a significant increase in the cholesterol content in GAT, SAT, and MAT in ABC1−/−/− mice compared with wild-type control mice (ABCA1+/+) on a chow diet (Fig. 1B). Following an HFHC diet, we observed a significant increase of cholesterol in GAT, SAT, and BAT in ABC1−/−/− mice (Fig. 1C).

To maintain intracellular cholesterol homeostasis, cholesterol has been shown to regulate the expression of genes affecting cholesterol metabolism via SREBP2 and the liver X receptor (LXR) (16, 17, 23). Thus, we evaluated how the loss of adipocyte ABC1 affects the expression of genes involved in maintaining cholesterol homeostasis. An increase in abcg1 mRNA expression as well as a reduction in ldlr gene expression and LDLR protein levels was observed (Fig. 1D, E). ABCG1 is a cholesterol transporter important in the maintenance of tissue cholesterol homeostasis by mediating cholesterol efflux to HDL (24). The LDLR mediates uptake of cholesterol by cells (25, 26). Our results indicate that the loss of ABC1 significantly alters adipose tissue cholesterol homeostasis and that adipocytes compensate for disturbances in lipid homeostasis by altering the expression of genes involved in cholesterol metabolism.

Adipocyte ABCA1 deficiency increases fat pad weight on an HFHC diet

Obesity is associated with the accumulation of both cholesterol and TGs in adipose tissue (3, 17). We evaluated whether changes in adipocyte ABCA1 expression and cholesterol content influence body weight, fat pad weight, and adipocyte TG levels.

On a chow diet, ABC1−/−/− mice demonstrated no difference in body weight, fat pad weight, and adipose tissue TG content compared with wild-type littermate controls (Fig. 2A, B). However, on an HFHC diet containing 21% milk fat (w/w) and 0.21% of cholesterol (w/w), ABC1−/−/− mice gain more weight than their littermate controls (Fig. 2C, D). To assess whether these changes in body weight gain were reflected in changes to adipose tissue mass, we isolated adipose tissue depots. Concomitant with increased body weight gain, SAT and BAT depots showed a significant increase in weight (Fig. 2E). To evaluate changes in TG content, we extracted lipids from different types of adipose tissue depots and observed that TG content was significantly increased in GAT, SAT, and MAT following correction for protein levels (Fig. 2F). Our results indicate that lack of adipocyte ABC1 leads to cholesterol accumulation, increased TG content in adipocytes, enlarged fat pads, and increased body weight.

Adipocyte ABCA1 deficiency alters lipolysis but does not lead to major changes in genes involved in TG metabolism

Adipose tissue stores large amounts of TGs, which can act as sources of energy and can be used to synthesize membrane and signaling lipids. However, in order to cross the adipocyte plasma membrane and be released into the plasma, adipocyte TGs must be hydrolyzed into fatty acids by a process known as lipolysis (6).

Sustained lipolysis has been shown to stimulate cholesterol efflux through ABCA1 (7). This suggests that there
Adipocyte ABCA1 is a crucial enzyme involved in TG biosynthesis was observed only in 10 major genes in TG metabolism. A significant increase in plasma cholesterol levels because of decreased efflux of cholesterol from adipose tissue in ABCA1<sup>−/−</sup> ad mice. We would expect decreases in plasma cholesterol levels because of decreased efflux of cholesterol from adipose tissue in ABCA1<sup>−/−</sup> ad mice. We indeed observed a decrease in plasma cholesterol levels; however, plasma levels of HDL cholesterol showed no significant difference (Table 1). There was a significant increase in plasma TG levels in ABCA1<sup>−/−</sup> ad mice (Table 1). Plasma NEFA levels were not significantly affected (Table 1).

Obesity and adipose dysfunction not only have consequences on plasma lipids but also have been associated with hepatic steatosis (21). Although the precise mechanism by which adipose tissue affects lipid accumulation in the liver remains unclear, increased NEFA flux, decreased adiponectin and visfatin expression, and insulin resistance may all play a role (1, 20, 21, 28). To assess the effect of adipose ABCA1 on the liver, we measured liver weight and hepatic lipid content in ABCA1<sup>−/−</sup> ad mice. After an HFHC diet, ABCA1<sup>−/−</sup> ad mice had an increased liver weight and demonstrated elevated levels of TG and cholesterol content in hepatic tissue (supplementary Fig. IIIA, B).

Adipocyte ABCA1 deficiency alters the expression of proteins involved in glucose homeostasis

Adipose tissue is critical in regulating whole-body glucose homeostasis through the release of adipokines such as leptin, adiponectin, and visfatin (1, 2). These act on various tissues including the pancreas to stimulate insulin secretion and the muscle to enhance insulin sensitivity. Low adiponectin levels are associated with reduced insulin secretion, insulin resistance, and hepatosteatosis. Visfatin is an insulin-mimicking protein, while leptin levels increase with weight gain and serve to regulate food intake and energy expenditure (1, 2, 20). Obesity and adipose dysfunction can alter adipokine expression and secretion.

We evaluated whether adipose tissue dysfunction due to the loss of ABCA1 could affect the expression of adipokine genes critical to whole-body glucose homeostasis. In ABCA1-deficient adipose tissue, we found that mRNA expression of leptin was significantly increased, whereas adiponectin and visfatin expression were significantly reduced (Fig. 4A). Plasma leptin and visfatin levels were unaltered (supplementary Fig. IID, E). HMW adiponectin levels showed a 30% decrease (P < 0.05) (Fig. 4C). These changes in adipokine expression may affect glucose tolerance.

GLUT-4 is a protein crucial for insulin-stimulated glucose uptake. Depletion of membrane adipocyte cholesterol by methyl-β-cyclodextrin in vivo reduces GLUT-4 mRNA expression and decreases insulin-stimulated glucose uptake (16). Moreover, GLUT-4 deficiency in adipose tissue has been shown to affect whole-body glucose tolerance (29). We evaluated whether ABCA1 affects GLUT-4 mRNA expression and GLUT-4 protein levels in adipose tissue. Both mRNA and protein expression of GLUT-4 were reduced in GAT from ABCA1<sup>−/−</sup> ad mice (Fig. 4A, B). The
changes in adipokine expression and reduced glut-4 expression suggest that adipose tissue dysfunction as a result of ABCA1 deficiency may impact whole-body glucose tolerance and insulin sensitivity.

Adipocyte ABCA1 deficiency impairs glucose tolerance, reduces insulin sensitivity, and impairs beta-cell function

We demonstrate that adipocyte ABCA1 deficiency increases cholesterol and TG storage in adipocytes and reduces adiponectin, visfatin, and glut-4 expression. These alterations in lipid homeostasis and gene expression are linked to impaired glucose tolerance and reduced insulin sensitivity (1, 2, 19, 20). Based on these findings, we hypothesize that adipocyte ABCA1 deficiency leads to glucose intolerance and insulin resistance in vivo.

To address this, we assessed glucose tolerance in ABCA1−/− ad/− ad versus control mice. Although we observed that glucose tolerance was unaltered in mice lacking adipocyte ABCA1 on a chow diet (data not shown), ABCA1−/− ad/− ad mice had significantly impaired glucose tolerance following an HFHC diet (Fig. 5A). To determine whether impaired glucose tolerance could be explained by a reduction in insulin sensitivity, we measured the response in plasma glucose levels after intraperitoneal insulin injection. A significant impairment of insulin sensitivity was observed in ABCA1−/− ad/− ad mice (Fig. 5C, D).

We then evaluated in which tissues insulin sensitivity was affected through measurement of AKT phosphorylation, a marker for intracellular insulin signaling. Because basal pAKT levels were too low to quantify (data not shown), we stimulated AKT phosphorylation by giving mice an intraperitoneal insulin injection followed by tissue extraction and immunoblotting analysis. Western blots revealed that the pAKT/AKT ratio was reduced in muscle from ABCA1−/− ad/− ad following insulin injection. The pAKT/AKT ratio was unaltered in adipose tissue (Fig. 5E, F). In the liver, AKT levels were very low, even following the injection of insulin, and we found no obvious changes in pAKT/AKT ratio (data not shown). Thus, adipocyte ABCA1 deficiency specifically impairs muscle tissue insulin sensitivity.

Blood was drawn from the saphenous vein after 4 h fasting and assessed for the parameters above. Values are means ± SEM. P values reaching statistical significance are bold. Chow: n = 15 (cholesterol, TG, glucose, HDL), n = 5–10 (insulin, NEFA); HFHC: n = 8–6.
In adipocytes is maintained by ABCA1 and is crucial for glucose homeostasis. Our data suggest that intracellular cholesterol homeostasis is a consequence of insulin resistance in tissues. Collectively, our findings support the paradigm that reduced beta-cell function can result from an increase in insulin demand as a consequence of insulin resistance (30, 31). Increased production of insulin may eventually lead to beta-cell failure and reduced insulin secretion in peripheral tissues results in increased insulin secretion by the pancreas to compensate for this insulin resistance (30, 31). Increased production of insulin may eventually lead to beta-cell failure and reduced insulin secretion (30, 31). This is consistent with our findings because ABCA1−/− mice demonstrated both decreased insulin sensitivity in muscle tissue and a significant increase in circulating plasma insulin levels on an HFHC diet (Table 1). To explore whether beta-cell function was affected, pancreatic islets were isolated from ABCA1−/− and wild-type mice and incubated in KRB buffer with low (1.67 mM) or high (16.67 mM) glucose, and insulin secretion in the media was measured. We observed that insulin secretion from beta cells was reduced in islets from ABCA1−/− mice after HFHC feeding (Fig. 5G). Our findings support the paradigm that reduced beta-cell function can result from an increase in insulin demand as a consequence of insulin resistance in tissues. Collectively, our data suggest that intracellular cholesterol homeostasis in adipocytes is maintained by ABCA1 and is crucial for glucose tolerance, insulin sensitivity, and beta-cell function.

**DISCUSSION**

Adipose tissue contains one of the largest pools of cholesterol in the body, is the primary storage depot for TGs, and is crucial in energy metabolism (20). Alterations in adipocyte cholesterol are associated with adipose dysfunction and obesity, and ABCA1 has been shown to mediate cholesterol efflux from adipose tissue (7, 9, 15). Adipose tissue dysfunction is an important risk factor for the development of glucose intolerance, insulin resistance, and type 2 diabetes (3, 19, 28); this indicates a role for adipocyte cholesterol and ABCA1 in these conditions.

Previous studies showing that cholesterol may be crucial in adipocyte function were mainly carried out in the 3T3 adipocyte cell line or observations in obese mice (3, 4, 16). In our study, we directly investigated how adipocyte ABCA1 affects adipose lipid content and adipocyte function using a mouse model specifically lacking ABCA1 in adipocytes. In this study, we demonstrated significantly increased intracellular cholesterol levels in the adipose tissue of ABCA1-deficient mice. Concomitant with increased cholesterol levels, we observed an enlargement of fat pads and an accumulation of TGs in the adipose tissue of ABCA1−/− mice on an HFHC diet. These changes in adipose tissue have significant metabolic consequences because we demonstrated that ABCA1−/− mice manifest impaired glucose tolerance, reduced muscle insulin sensitivity, and lower glucose-stimulated insulin secretion from beta cells ex vivo.

Using ABCA1−/− mice, we showed that cholesterol accumulates in ABCA1-deficient adipose tissue in mice on both a chow and an HFHC diet. This increase in cholesterol content is likely a direct effect of reduced ABCA1-mediated cholesterol efflux from adipose tissue. Increased intracellular cholesterol has a major impact on lipid metabolism because cholesterol regulates the expression of multiple genes involved in intracellular lipid homeostasis. For example, increased intracellular cholesterol reduces the expression of hmgcr and hmgcs2 and the ldlr via SREBP2 to reduce cholesterol synthesis and uptake (16, 17). In addition, the generation of oxysterols from intracellular cholesterol activates the LXR transcription factor, which increases the expression of cholesterol efflux genes including abca1 and abcg1 (16, 23). In this study, we observed decreased ldlr expression and an increase in abcg1 expression in ABCA1-deficient adipose tissue. We believe that the absence of ABCA1 induces cholesterol accumulation and influences various compensatory mechanisms to regulate cholesterol balance in adipocytes. Increased ABCG1 to enhance cholesterol efflux and decreased LDLR to reduce cholesterol uptake suggest that compensatory mechanisms are conserved in the adipocyte to regulate cholesterol homeostasis.

It has been suggested that intracellular cholesterol influences TG stores in adipose tissue (3, 17). This hypothesis is also supported by our data because we observed that ABCA1-deficient adipose tissue accumulates TGs and cholesterol in response to an HFHC diet. It has been shown in vitro that increased ABCA1-mediated cholesterol efflux from adipocytes occurs following the stimulation of TG lipolysis (7, 8). This may indicate a possible link between ABCA1 and TG lipolysis in adipocytes. We demonstrated that TG lipolysis is reduced ex vivo in adipose tissue from ABCA1−/− mice. This suggests that ABCA1 may directly influence TG levels and lipolysis. Reduced TG lipolysis
may contribute to the TG accumulation we observed in adipose tissue from ABCA1<sup>−/−</sup> mice on an HFHC diet. We ruled out feeding behavior causing weight gain because we did not observe a difference in food intake between ABCA1<sup>−/−</sup> mice and control littermates (supplementary Fig. IIC).

ABCA1<sup>−/−</sup> mice demonstrated increased body weight, impairment in glucose tolerance, and increased insulin resistance on an HFHC diet. This suggests that adipocyte ABCA1 is crucial for proper adipose tissue function in response to dietary fat and cholesterol. Our observations also indicate that loss of adipocyte ABCA1 and subsequent increase in intracellular cholesterol levels are sufficient to influence whole-body glucose tolerance. Increased body weight and adipocyte TG accumulation are associated with adipocyte dysfunction, which may lead to a number of metabolic disturbances including glucose intolerance, insulin resistance, and hepatosteatosis (18, 19, 21, 32).

Metabolic disturbances are affected by adipose tissue through the release of NEFAs and adipokines in plasma (1, 2, 19, 20). Increased NEFA flux from adipose tissue to liver, muscle, and pancreas has been shown to reduce insulin sensitivity and secretion (19, 21). However, we did not observe significantly altered NEFA levels in the plasma of our ABCA1<sup>−/−</sup> mice. Expression and release of adiponectin shows an inverse correlation with adipose mass (2, 19, 21). Decreased levels of adiponectin reduce insulin sensitivity and stimulate hepatic lipid accumulation (2, 19, 21). In our ABCA1<sup>−/−</sup> model, we observed reduced adiponectin, gene expression, and a reduction in visfatin and GLUT-4 gene expression along with increased leptin expression. In plasma, we observed a decrease in HMW adiponectin, which is the metabolically most active form of adiponectin. This decrease in plasma HMW adiponectin may therefore contribute to the insulin resistance and glucose intolerance, as well as the hepatic lipid accumulation, we observed in our mouse model. GLUT-4 deficiency in adipose tissue has been shown to impair whole-body glucose tolerance and muscle insulin resistance, but this effect is independent of circulating NEFAs, TGs, or leptin (29). This suggests that other unknown mechanisms associated with GLUT-4 may play a role in modulating insulin resistance.

In an effort to identify other mechanisms by which adipocyte ABCA1 deficiency affects whole-body glucose homeostasis, we investigated the expression of genes and proteins involved in glucose metabolism in the liver. We did not observe altered levels of pAKT in the liver. Expression of the gluconeogenesis genes phosphoenolpyruvate carboxykinase and glucose 6-phosphatase in the liver were also unaltered (data not shown). We cannot exclude, however, that the hepatosteatosis we observed in ABCA1<sup>−/−</sup> mice could contribute to glucose intolerance by altering hepatic glucose output or uptake (21).

When blood glucose levels rise due to insulin resistance, the pancreas attempts to compensate by increasing beta-cell insulin secretion. However, elevated insulin secretion may eventually result in beta-cell dysfunction and failure (31, 33, 34). We observed that adipocyte-specific ABCA1...
